# Three Dimensional Viewing

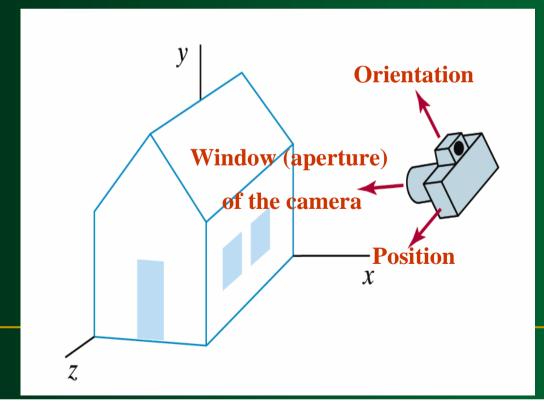

## 3D Viewing

The steps for computer generation of a view of a three dimensional scene are somewhat analogous to the processes involved in taking a photograph.

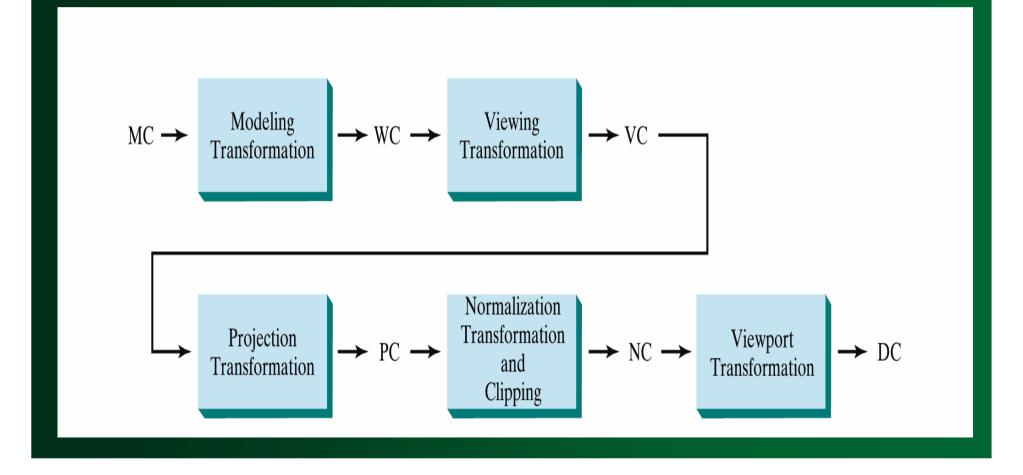

## Camera Analogy

- 1. Viewing position
- 2. Camera orientation
- 3. Size of clipping window

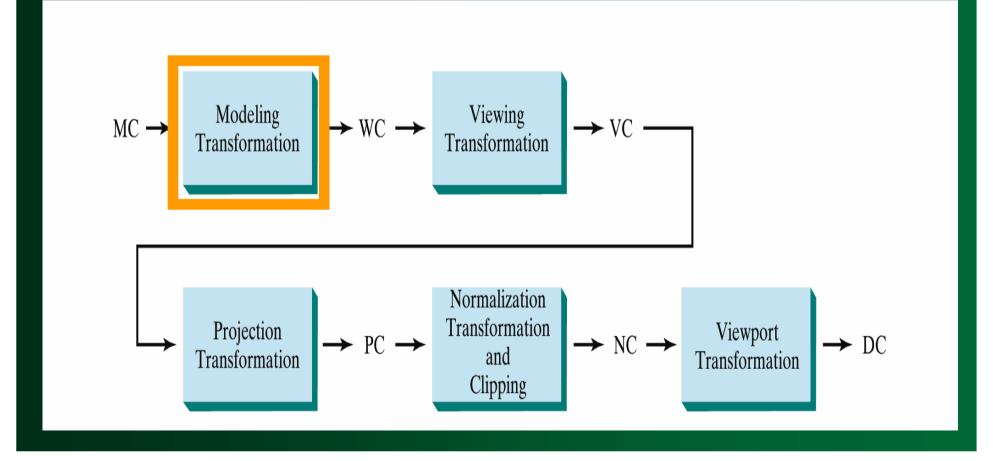

## Viewing Pipeline

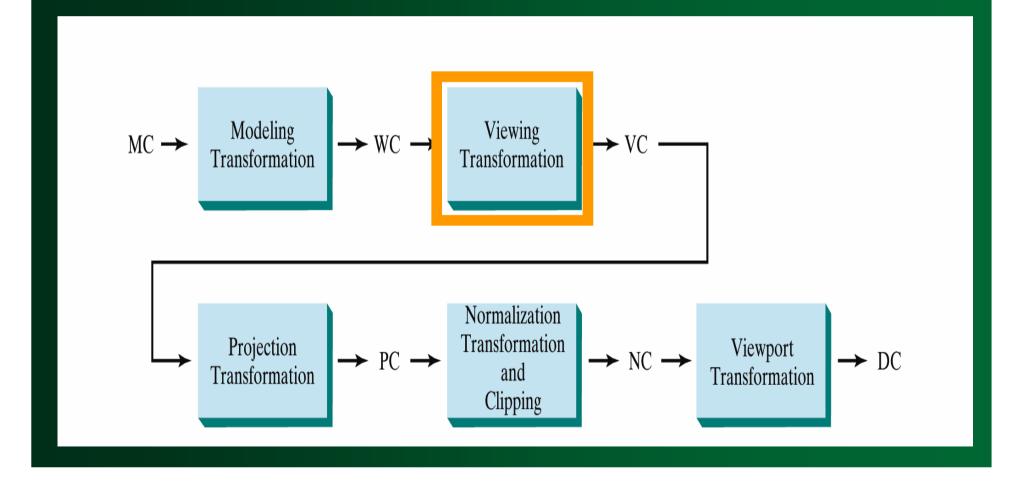

The general processing steps for modeling and converting a world coordinate description of a scene to device coordinates:

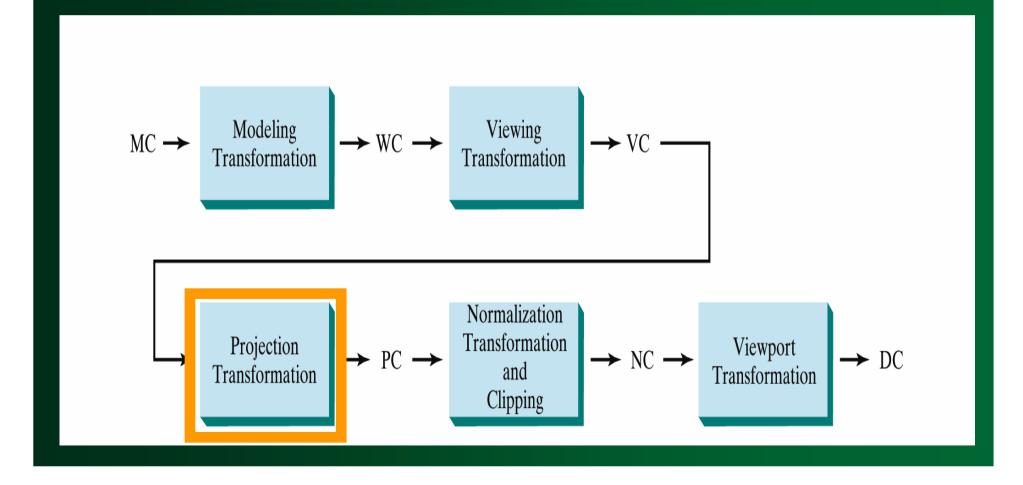

Viewing Pipeline
Construct the shape of individual objects in a scene within modeling coordinate, and place the objects into appropriate positions within the scene (world coordinate).

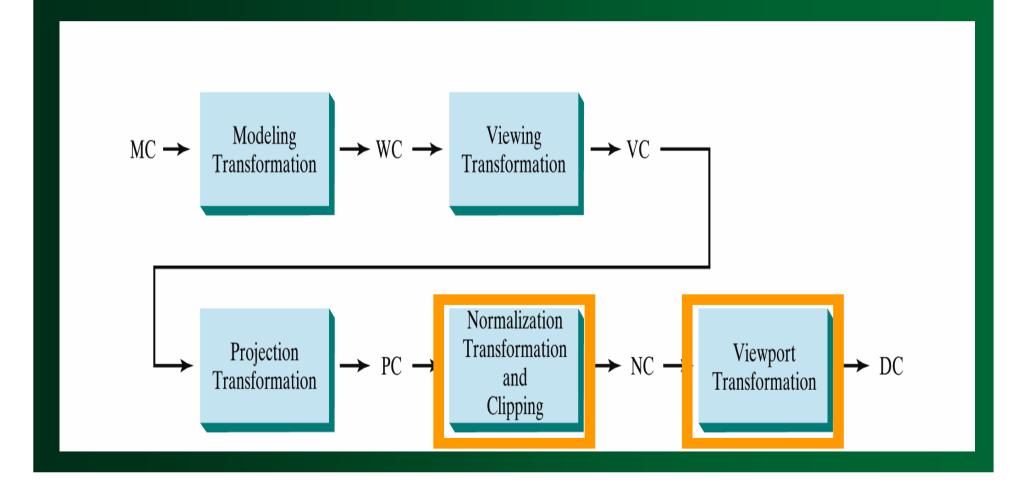

Viewing Pipeline
World coordinate positions are converted to viewing coordinates.

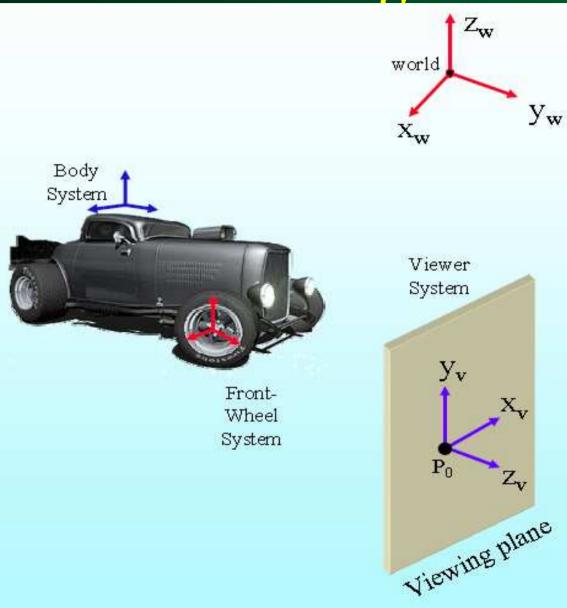

Viewing Pipeline
Convert the viewing coordinate description of the scene to coordinate positions on the projection plane.

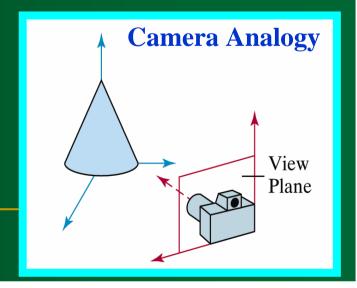

Viewing Pipeline
Positions on the projection plane, will then mapped to the Normalized coordinate and output device.

## **Viewing Coordinates**

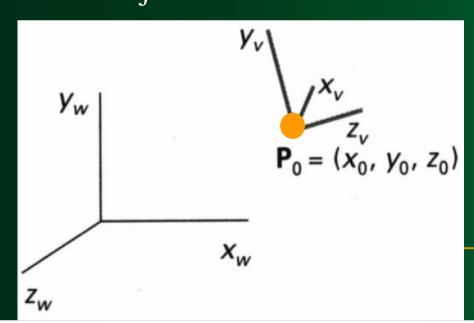

- Viewing coordinates
  system describes 3D
  objects with respect to a
  viewer.
- A Viewing (Projector) plane is set up perpendicular to  $z_v$  and aligned with  $(x_v, y_v)$ .

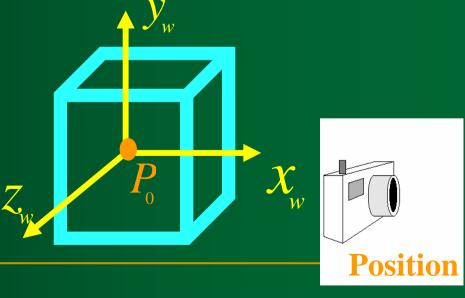

## **Specifying the Viewing Coordinate System (View Reference Point)**

- We first pick a world coordinate position called view
   reference point (origin of our viewing coordinate system).
- $\mathbf{P}_0$  is a point where a camera is located.

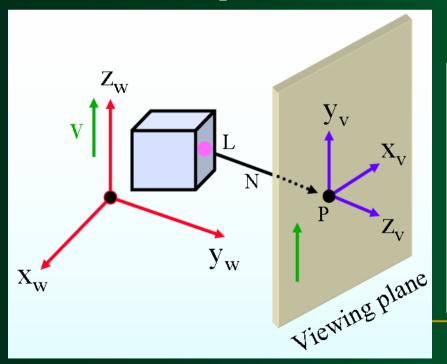

The view reference point is often chosen to be close to or on the surface of some object, or at the center of a group of objects.

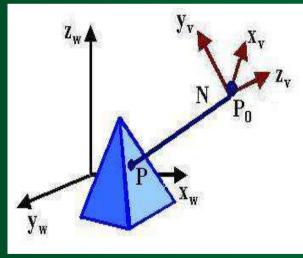

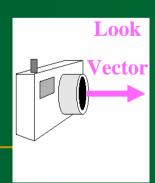

## Specifying the Viewing Coordinate System $(Z_v Axis)$

- Next, we select the positive direction for the viewing  $\mathbf{z}_{\mathbf{v}}$  axis, by specifying the view plane normal vector, N.
- The direction of N, is from the look at point (L) to the view reference point.

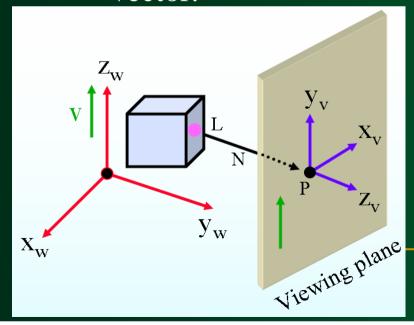

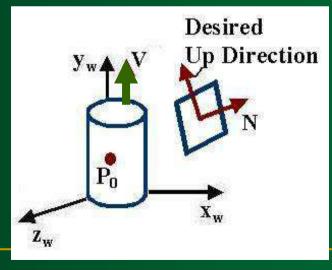

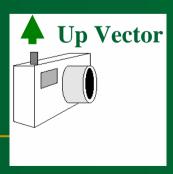

## Specifying the Viewing Coordinate System (y, Axis) Finally, we choose the *up direction* for the view by

- Finally, we choose the up direction for the view by specifying a vector V, called the view up vector.
- This vector is used to establish the positive direction for the  $y_v$  axis.
- V is projected into a plane that is perpendicular to the normal vector.

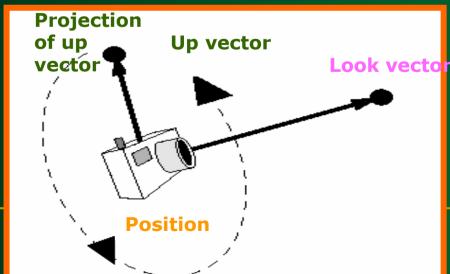

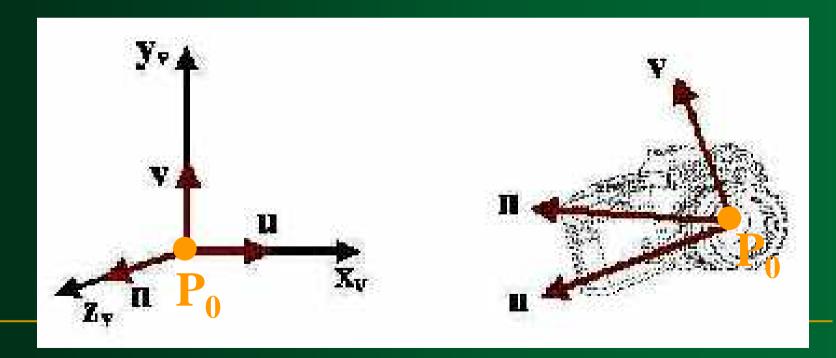

## Look and Up Vectors

- Look Vector
- the direction the camera is pointing
- three degrees of freedom; can be any vector in 3-space
- Up Vector
  - determines how the camera is rotated around the Look vector
  - for example, whether you're holding the camera horizontally or vertically (or in between)
  - <u>projection</u> of *Up vector* must be in the plane perpendicular to the look vector

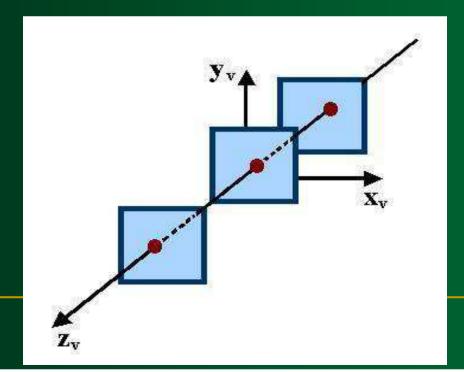

## **Specifying the Viewing Coordinate System (x<sub>v</sub> Axis)**

Using vectors  $\mathbf{N}$  and  $\mathbf{V}$ , the graphics package computer can compute a third vector  $\mathbf{U}$ , perpendicular to both  $\mathbf{N}$  and  $\mathbf{V}$ , to define the direction for the  $\mathbf{X}_{\mathbf{v}}$  axis.

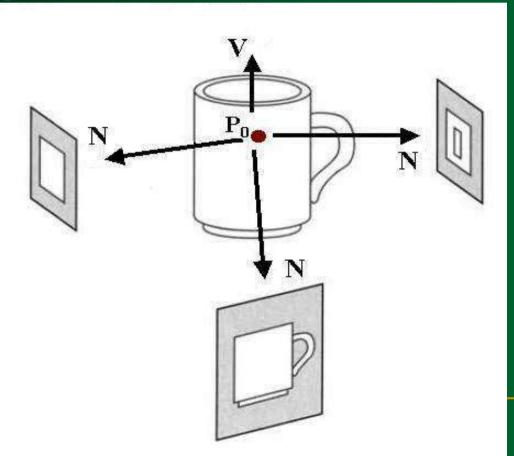

#### The View Plane

- Graphics package allow users to choose the position of the view plane along the z<sub>v</sub> axis by specifying the view plane distance from the viewing origin.
- The view plane is always parallel to the  $x_v y_v$  plane.

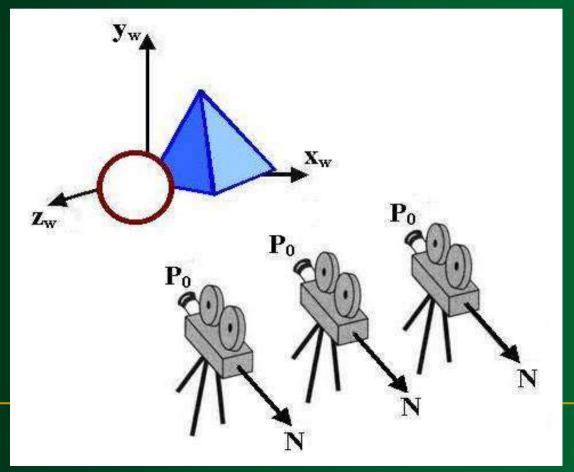

#### Obtain a Series of View

To obtain a series of view of a scene, we can keep the view reference point fixed and change the direction of N.

#### **Simulate Camera Motion**

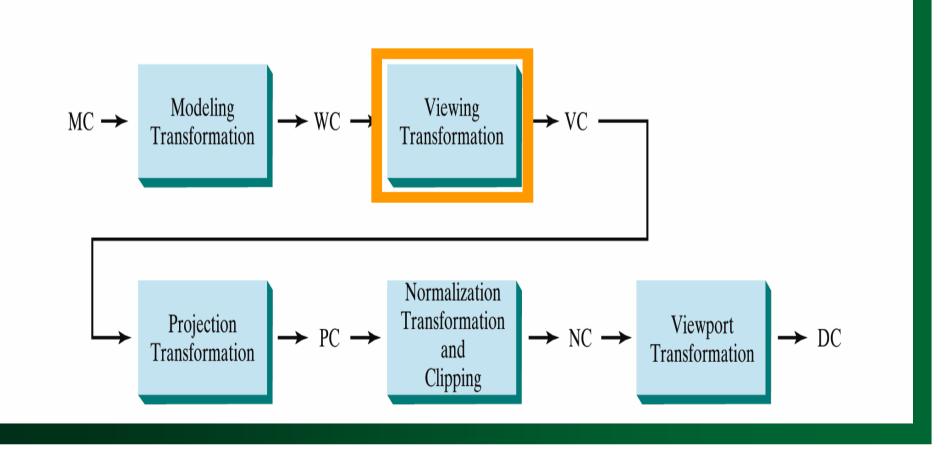

To simulate camera motion through a scene, we can keep N fixed and move the view reference point around.

# Transformation from World to Viewing Coordinates

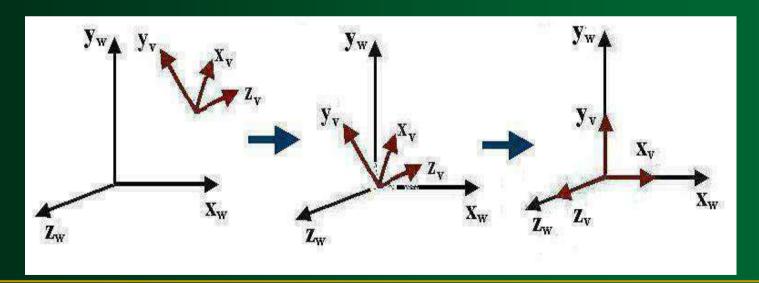

## Viewing Pipeline

- Before object description can be projected to the view plane, they must be transferred to viewing coordinates.
- World coordinate positions are converted to viewing coordinates.

## Transformation from World to Viewing Coordinates

- Transformation sequence from world to viewing coordinates:
- Translate the view reference point to the origin of the world-coordinate system.
- Apply rotations to align the  $x_v$ ,  $y_v$  and  $z_v$  axes with the world  $x_w$ ,  $y_w$  and  $z_w$  axes.

$$\mathbf{M}_{WC,VC} = \mathbf{R}_z \cdot R_y \cdot R_x.\mathbf{T}$$

## Transformation from World to Viewing Coordinates

- Another Method for generating the rotationtransformation matrix is to calculate unit UVN vectors and form the composite rotation matrix directly:
- Given vectors V and N:

$$\mathbf{n} = \frac{\mathbf{N}}{|\mathbf{N}|} = (n_1, n_2, n_3)$$

$$\mathbf{u} = \frac{\mathbf{V} \times \mathbf{N}}{|\mathbf{V} \times \mathbf{N}|} = (u_1, u_2, u_3)$$

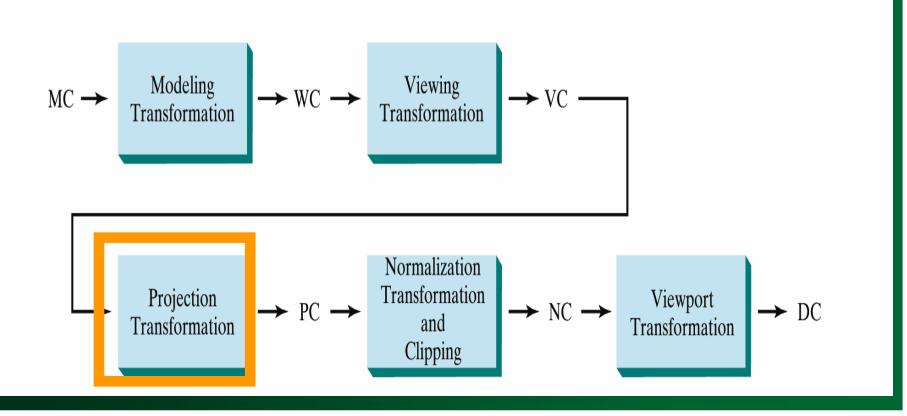

$$\mathbf{v} = \mathbf{n} \times \mathbf{u} = (v_1, v_2, v_3)$$

$$\mathbf{R} = \begin{bmatrix} u_1 & u_2 & u_3 & 0 \\ v_1 & v_2 & v_3 & 0 \\ n_1 & n_2 & n_3 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

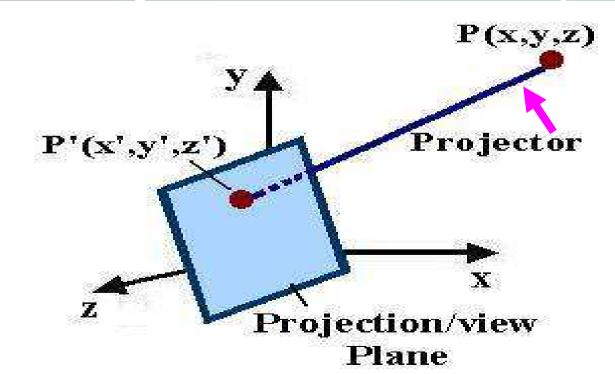

$$\mathbf{M}_{WC,VC} = \mathbf{R} \cdot \mathbf{T}$$

## Viewing Pipeline

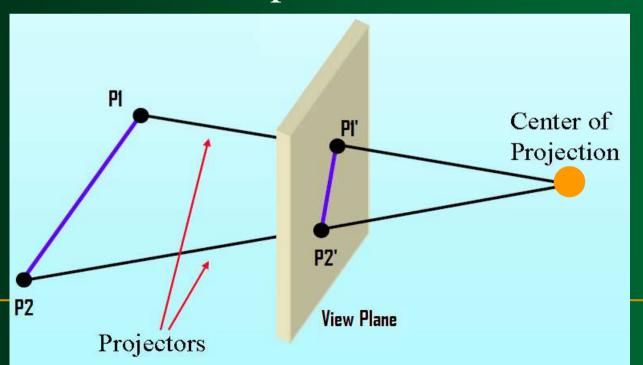

- Convert the viewing coordinate description of the scene to coordinate positions on the projection plane.
- Viewing 3D objects on a 2D display requires a mapping from 3D to 2D.

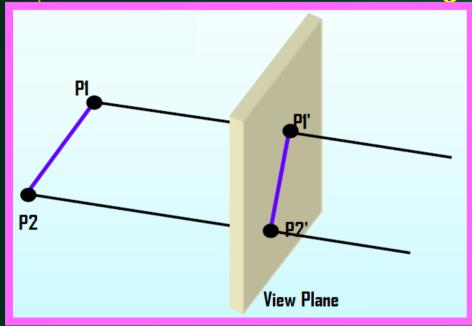

- Projection can be defined as a mapping of point P(x,y,z) onto its image P'(x',y',z') in the projection plane.
- The mapping is determined by a **projector** that passes through P and intersects the view plane (P').

- Projectors are lines from center (reference) of projection through each point in the object.
- The projected view of the object is determined by calculating the intersection of projection lines with the view plane.

Projection or Reference Point

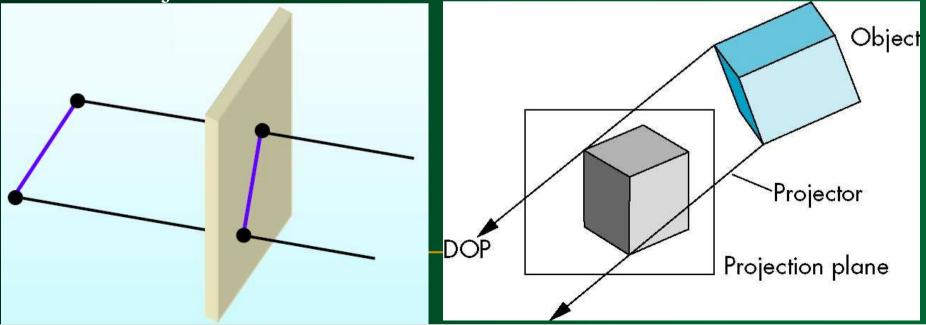

Object positions are transformed to the view plane along lines that converge to the projection reference (center) point.

#### Parallel Projection:

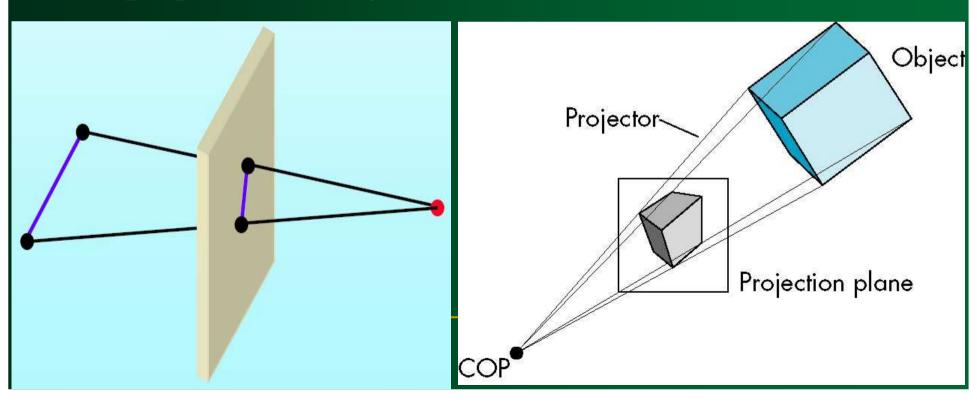

Coordinate positions are transformed to the view plane along parallel lines.

## **Parallel Projection**

- Coordinate position are transformed to the view plane along parallel lines.
- Center of projection at infinity results with a parallel projection.
- A parallel projection preserves relative proportion of objects, but does not give us a realistic representation of the appearance of object.

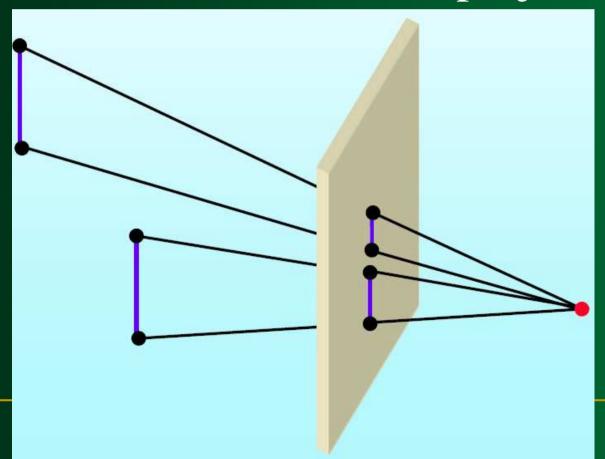

- Perspective Projection
  Object positions are transformed to the view plane along lines that converge to the projection reference (center) point.
- Produces realistic views but does not preserve relative proportion of objects.

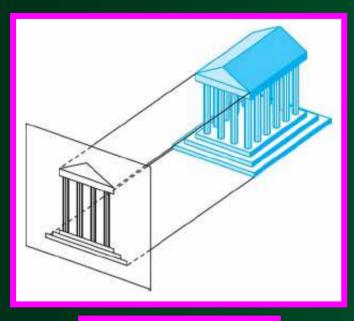

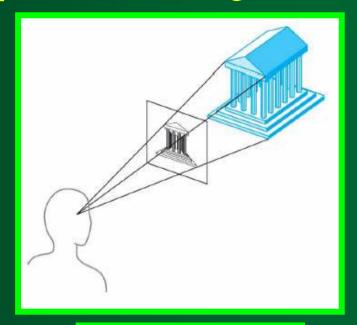

#### **Perspective Projection**

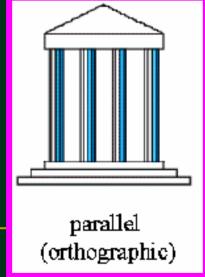

Projections of distant objects are smaller than the projections of objects of the same size that are closer to the projection plane.

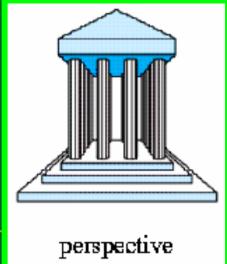

## Parallel and Perspective Projection

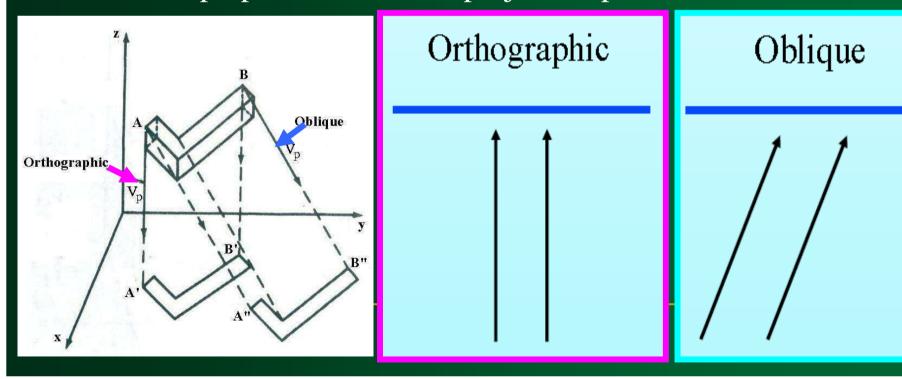

## Parallel Projection

### Parallel Projection

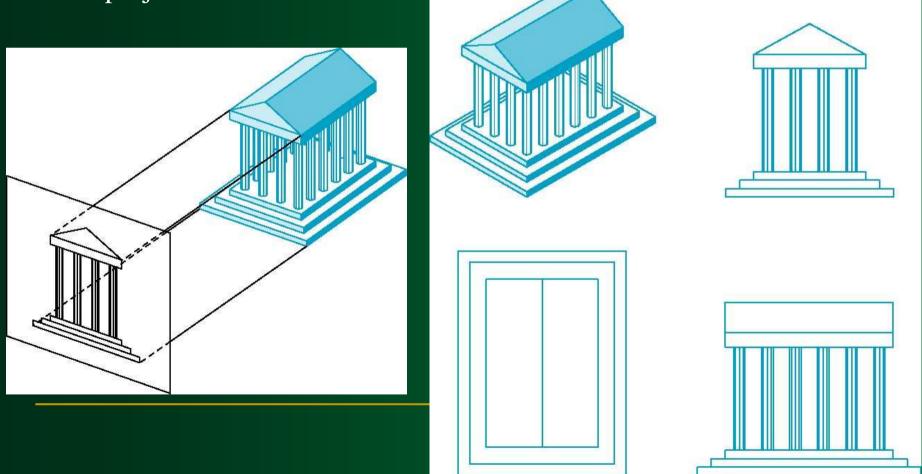

- Projection vector: Defines the direction for the projection lines (projectors).
- Orthographic Projection: Projectors (projection vectors) are perpendicular to the projection plane.
- Oblique Projection: Projectors (projection vectors) are
   not perpendicular to the projection plane.

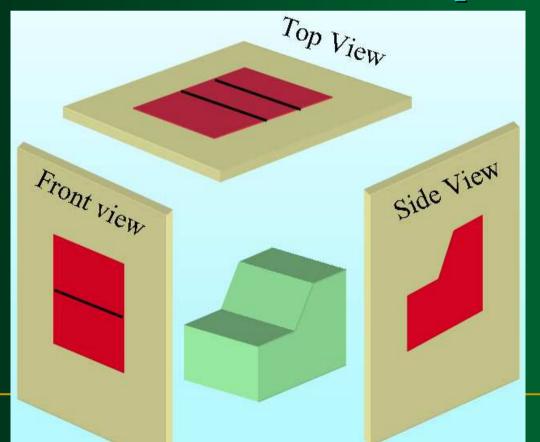

Orthographic projection used to produce the front, side, and top views of an object.

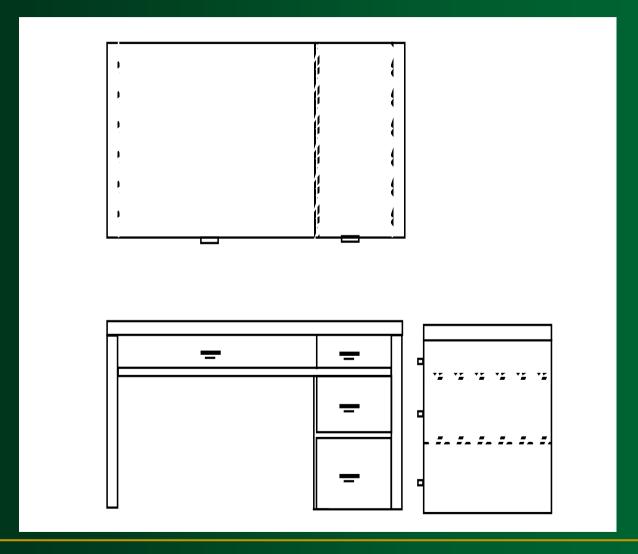

Engineering and architectural drawings employ orthographic

projections.

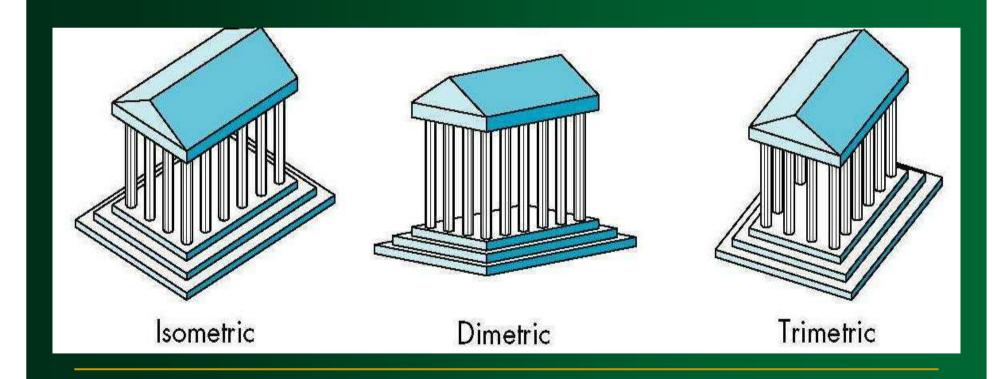

- **Front**, **side**, and **rear** orthographic projections of an object are called **elevations**.
- **Top** orthographic projection is called a **plan** view.

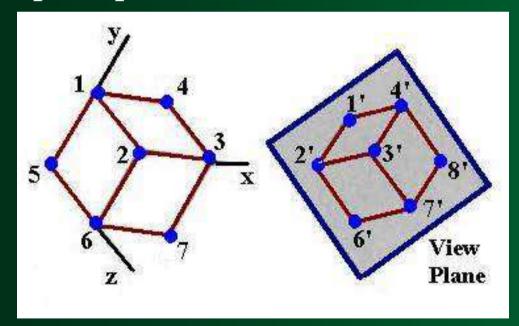

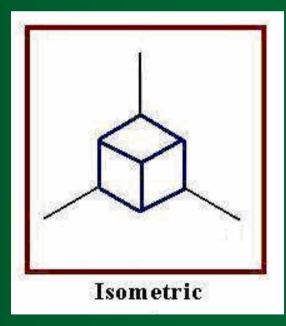

Multi View Orthographic

**Axonometric orthographic** projections display more than one face of an object.

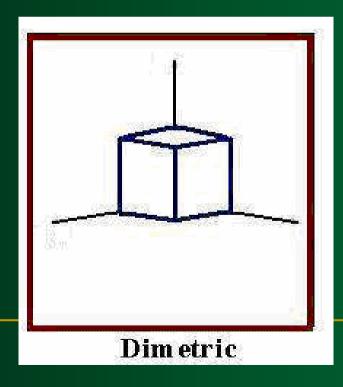

- **Isometric Projection**: Projection plane intersects each coordinate axis in which the object is defined (principal axes) at the same distant from the origin.
- Projection vector makes equal angles with all of the three principal axes.

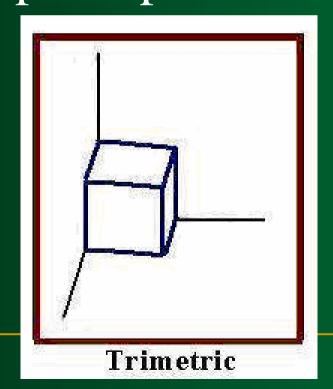

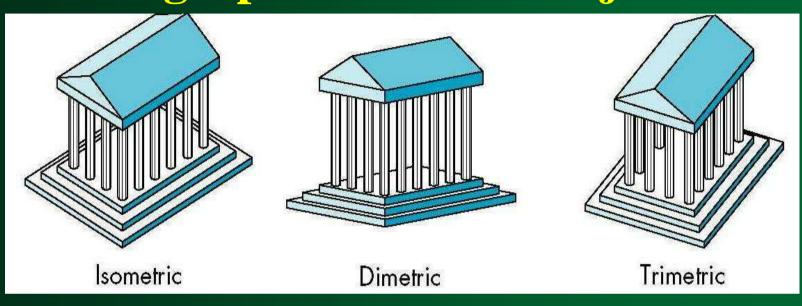

Isometric projection is obtained by aligning the projection vector with the cube diagonal.

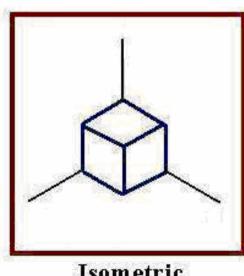

**Dimetric Projection:** Projection vector makes **equal angles** with exactly **two** of the principal axes.

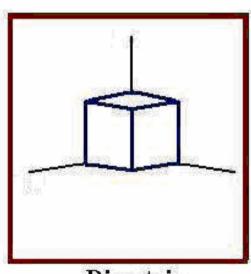

Trimetric Projection: Projection vector makes unequal angles with the three principal axes.

Trimetric

# Orthographic Parallel Projection Transformation

# Orthographic Parallel Projection Transformation

Convert the viewing coordinate description of the scene to coordinate positions on the Orthographic parallel projection plane.

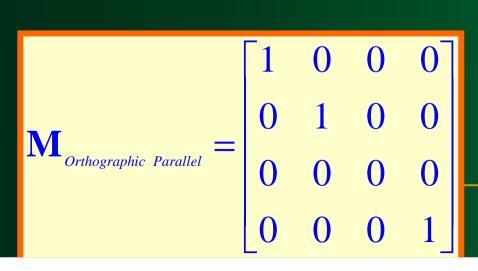

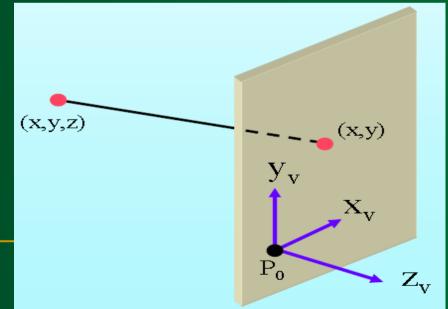

# Orthographic Parallel Projection Transformation

Since the view plane is placed at position  $z_{vp}$  along the  $z_{v}$  axis. Then any point (x,y,z) in viewing coordinates is transformed to projection coordinates as:

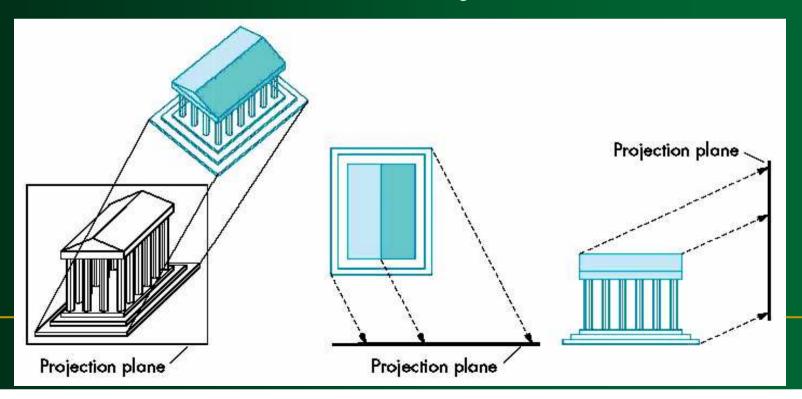

$$x_p = x$$
,  $y_p = y$ 

The original z-coordinate value is preserved for the depth information.

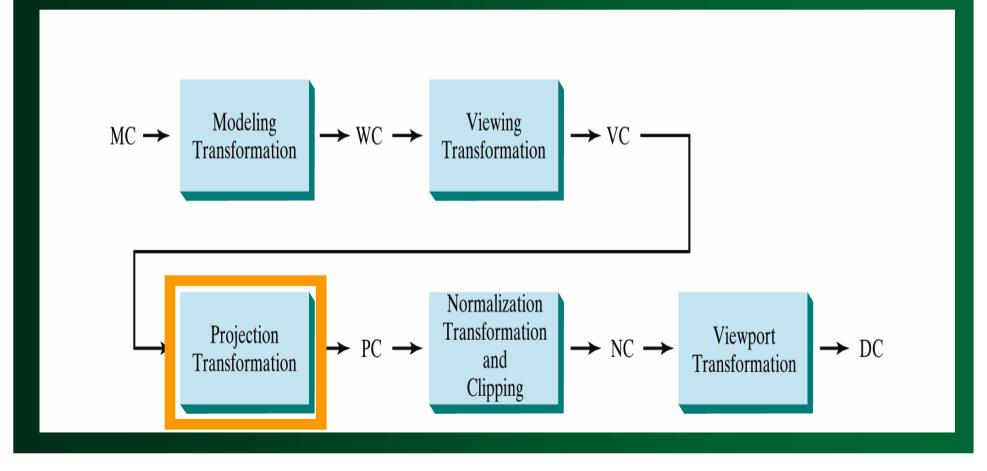

- Projections are not perpendicular to the viewing plane.
- Angles and lengths are preserved for faces parallel to the plane of projection.
- Preserves 3D nature of an object.

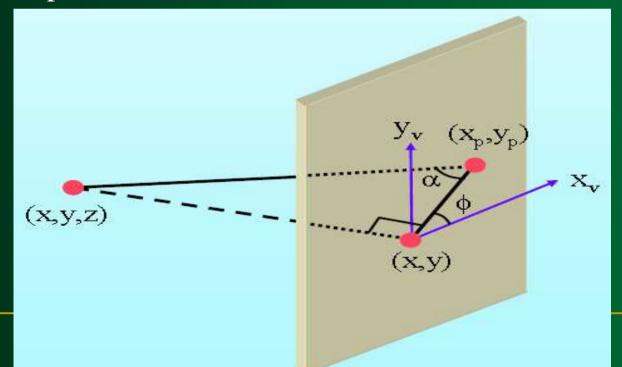

# Oblique Parallel Projection Transformation

# Oblique Parallel Projection Transformation

Convert the viewing coordinate description of the scene to coordinate positions on the Oblique parallel projection plane.

- Point (x,y,z) is projected to position  $(x_p,y_p)$  on the view plane.
- Projector (oblique) from (x,y,z) to  $(x_p,y_p)$  makes an angle  $(x_p,y_p)$  with the line (of length L) on the projection plane that joins  $(x_p,y_p)$  and (x,y).
- Line L is at an angle  $\phi$  with the horizontal direction in the projection plane.

$$x_p = x + L\cos\varphi$$

$$y_p = y + L\sin\varphi$$

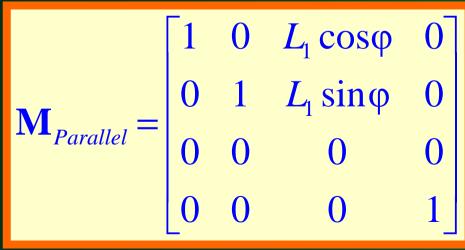

$$\tan \alpha = \frac{z}{L}$$

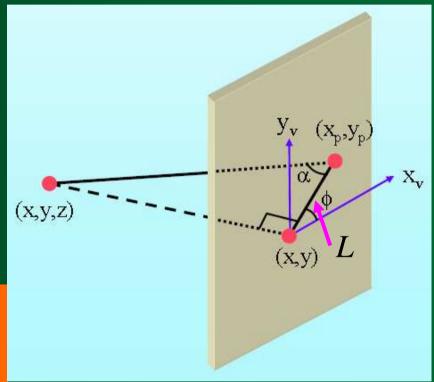

$$L = \frac{z}{\tan \alpha}$$

$$= zL_1$$

$$x_p = x + z(L_1 \cos \varphi)$$

$$x_p = x + z(L_1 \cos \varphi)$$
$$y_p = y + z(L_1 \sin \varphi)$$

#### Orthographic Projection:

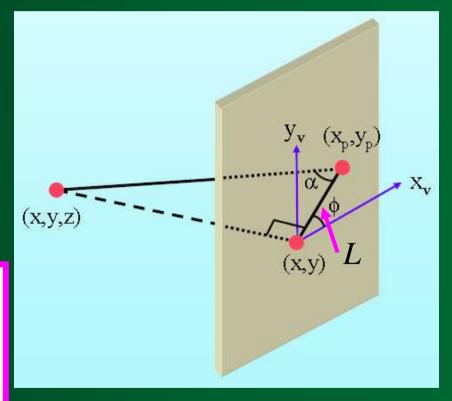

$$L_1 = 0$$

$$\alpha = 90^{\circ}$$

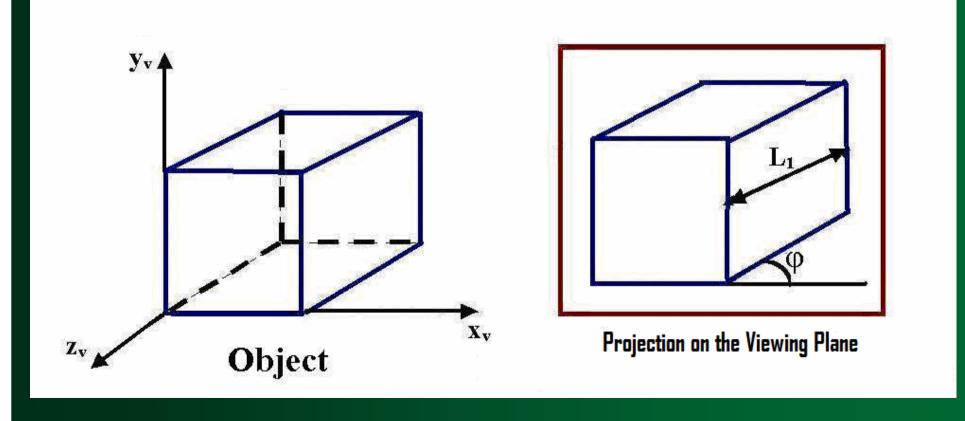

$$\alpha = 90^{\circ}$$

$$x_p = x$$
,  $y_p = y$ 

$$\mathbf{M}_{Orthographic\ Parallel} = egin{bmatrix} 1 & 0 & 0 & 0 \ 0 & 1 & 0 & 0 \ 0 & 0 & 0 & 0 \ 0 & 0 & 0 & 1 \end{bmatrix}$$

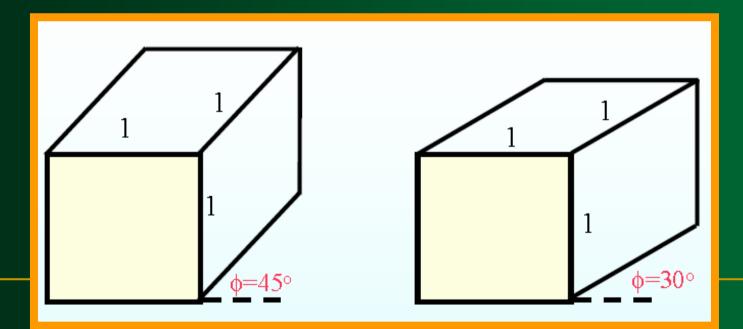

Angles, distances, and parallel lines in the plane are projected accurately.

### Cavalier Projection Cavalier Projection:

$$\phi = 30^{\circ}$$
 and  $45^{\circ}$   $\tan \alpha = 1$   $\alpha = 45^{\circ}$ 

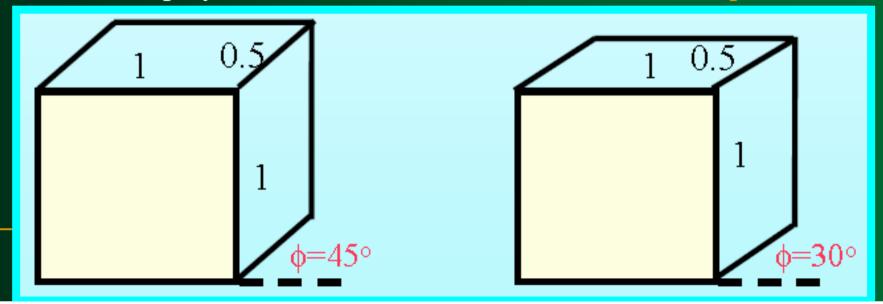

- Preserves lengths of lines perpendicular to the viewing plane.
- **3D** nature can be captured but shape seems distorted.
- Can display a combination of front, and side, and top views.

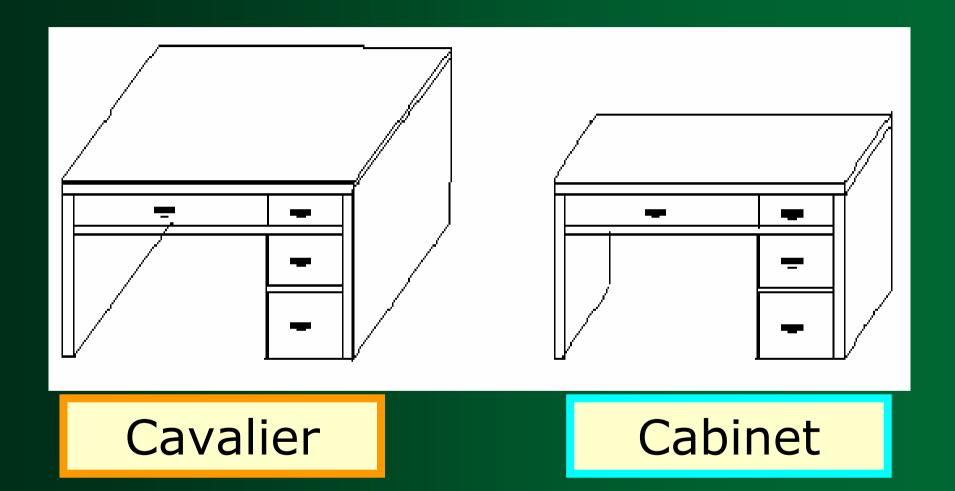

# Cabinet Projection Cabinet Projection:

$$\phi = 30^{\circ}$$
 and  $45^{\circ}$   $\tan \alpha = 2$   $\alpha \approx 63.4^{\circ}$ 

- Lines perpendicular to the viewing plane are projected at  $\frac{1}{2}$  of their length.
- A more realistic view than the cavalier projection.
- Can display a combination of front, and side, and top views.

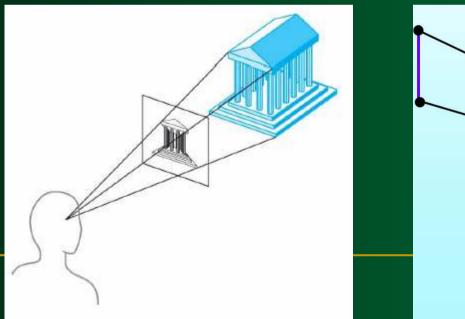

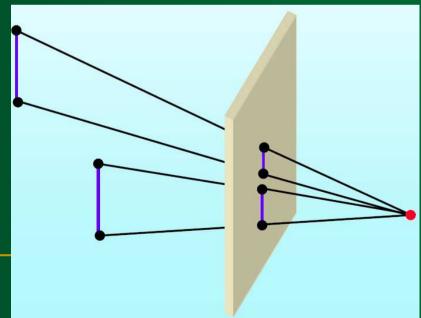

#### Cavalier & Cabinet Projection

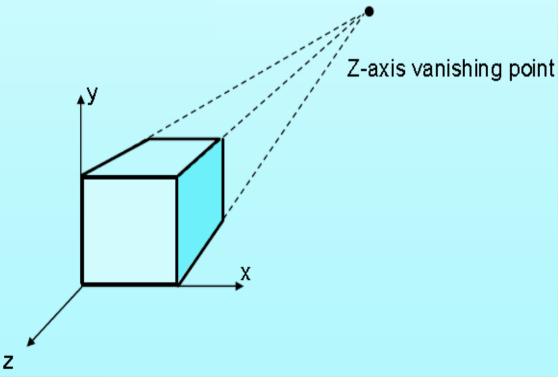

- In a perspective projection, the center of projection is at a finite distance from the viewing plane.
- Produces realistic views but does not preserve relative proportion of objects
- The size of a projection object is inversely proportional to its distance from the viewing plane.

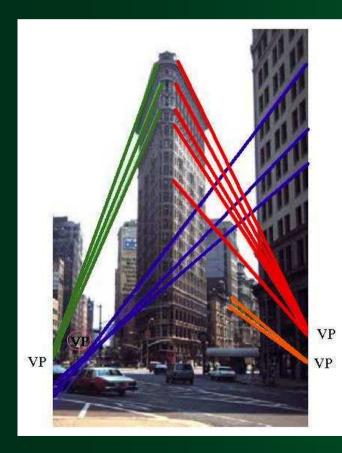

- Parallel lines that are not parallel to the viewing plane, converge to a vanishing point.
- A vanishing point is the projection of a point at infinity.

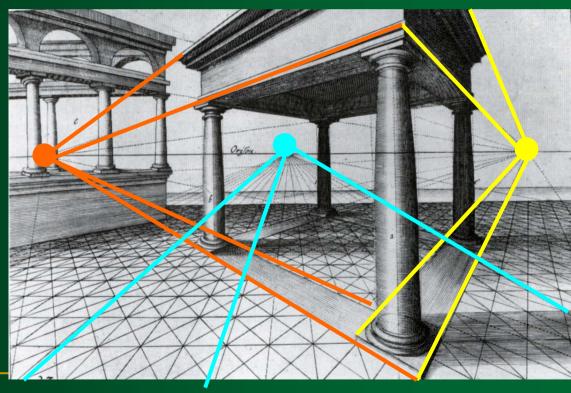

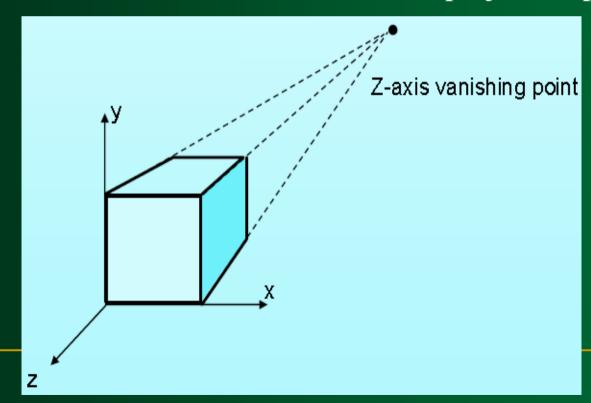

#### Vanishing Points

Each set of projected parallel lines will have a separate vanishing points.

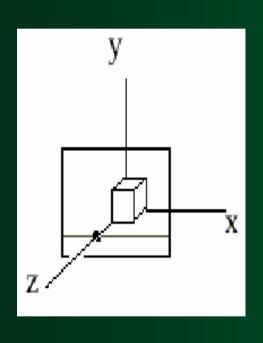

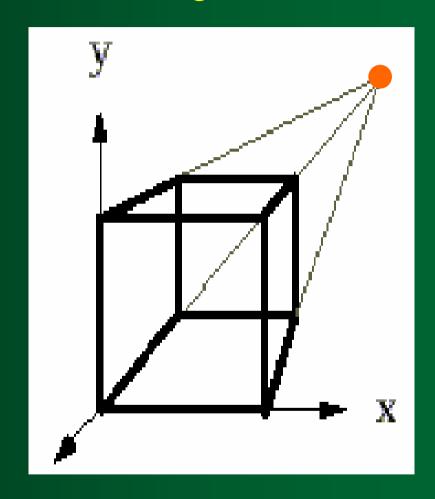

- The vanishing point for any set of lines that are parallel to one of the principal axes of an object is referred to as a principal vanishing point.
- We control the number of principal vanishing points (one, two, or three) with the orientation of the projection plane.

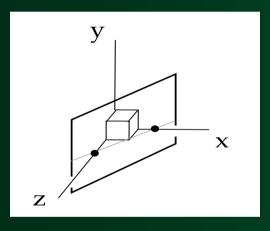

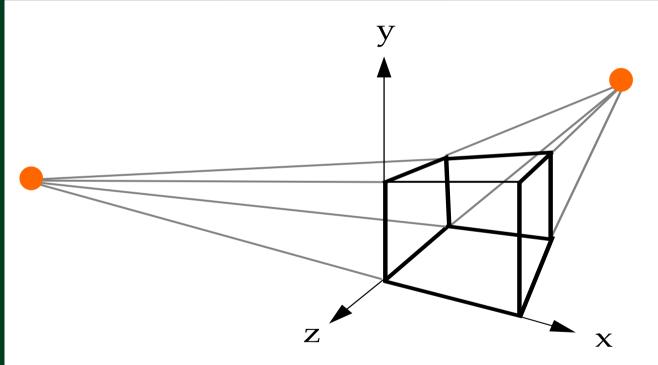

The number of principal vanishing points in a projection is determined by the number of principal axes intersecting the view plane.

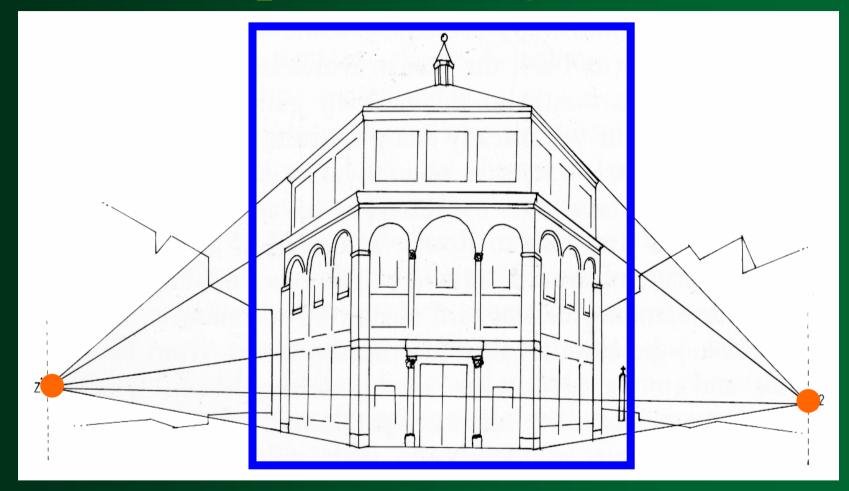

One Point Perspective (z-axis vanishing point)

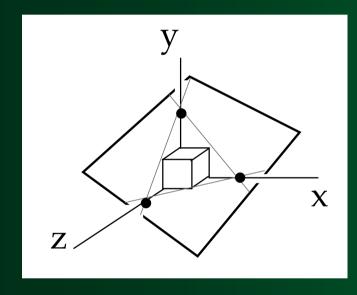

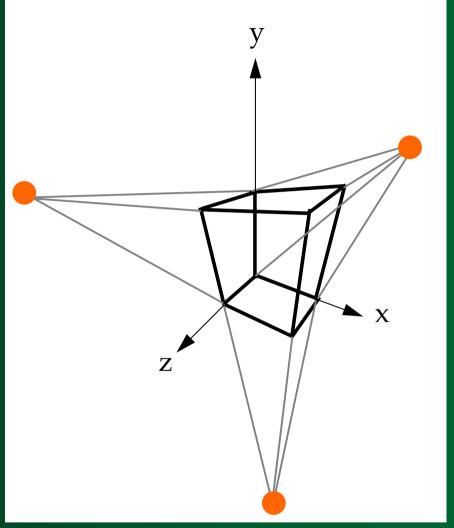

#### Two Point Perspective

(z, and x-axis vanishing points)

Two Point Perspective

#### Three Point Perspective

(z, x, and y-axis vanishing points)

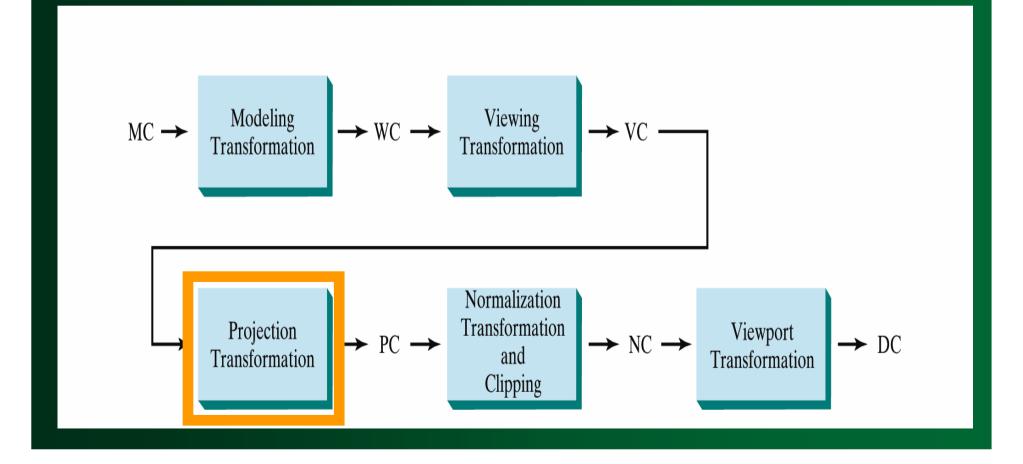

**One-Point Perspective Projection** 

**Two-Point Perspective Projection** 

**Tree-Point Perspective Projection** 

Convert the viewing coordinate description of the scene to coordinate positions on the perspective projection plane.

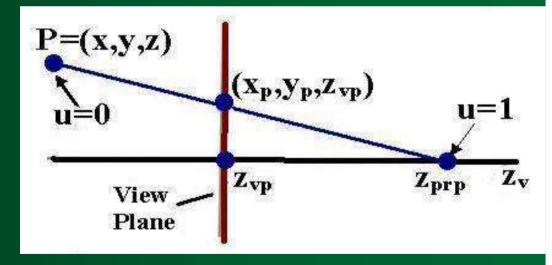

To obtain a perspective projection of a three dimensional object, transform points along the projection lines that meet a projection reference point.

Set the projection reference point at position  $z_{prp}$  along the  $z_v$ 

axis.

Set the view plane at Z<sub>vp</sub>.

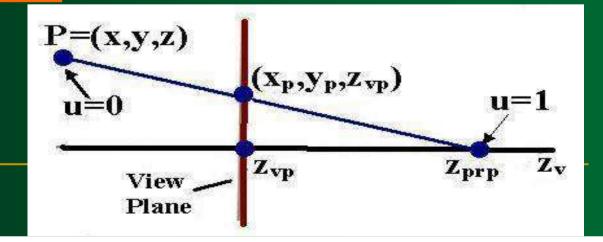

- Suppose the projection reference point at position  $z_{prp}$  along the  $z_v$  axis, and the view plane at  $z_{vp}$ .
- Equations of the perespective projection line in parametric form as

$$x' = x - xu$$

$$y' = y - yu$$

$$z' = z - (z - z_{prp})u$$

$$0 \le u \le 1$$

On the view plane: 
$$z' = z_{vp}$$

$$u = \frac{z_{vp} - z}{z_{prp} - z} \qquad d_p = z_{prp} - z_{vp}$$

$$x_{p} = x \left( \frac{z_{prp} - z_{vp}}{z_{prp} - z} \right) = x \left( \frac{d_{p}}{z_{prp} - z} \right)$$

$$y_{p} = y \left( \frac{z_{prp} - z_{vp}}{z_{prp} - z} \right) = y \left( \frac{d_{p}}{z_{prp} - z} \right)$$

dp is the distance of the view plane from the projection reference point

The perspective projection transformation of threedimensional can be represented using homogeneous

coordinates:  $x_p = x_h/h$ ,  $y_p = y_h/h$ The homogeneous factor is:  $h = \frac{z_{prp} - z}{d_p}$ 

$$h = \frac{z_{prp} - z}{d_p}$$

$$\begin{bmatrix} x_h \\ y_h \\ z_h \\ h \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -z_{vp}/d_p & z_{vp}(z_{prp}/d_p) \\ 0 & 0 & -1/d_p & z_{prp}/d_p \end{bmatrix} \cdot \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix}$$

#### Special Cases:If view plane is uv plane

$$z_{vp} = 0$$

$$x_{p} = x \left( \frac{z_{prp} - z_{vp}}{z_{prp} - z} \right) = x \left( \frac{d_{p}}{z_{prp} - z} \right)$$

$$y_{p} = y \left( \frac{z_{prp} - z_{vp}}{z_{prp} - z} \right) = y \left( \frac{d_{p}}{z_{prp} - z} \right)$$

$$z_{prp} = z \left( \frac{d_{p}}{z_{prp} - z} \right)$$

$$x_{p} = x \left(\frac{z_{prp} - z_{vp}}{z_{prp} - z}\right) = x \left(\frac{d_{p}}{z_{prp} - z}\right)$$

$$x_{p} = x \left(\frac{z_{prp}}{z_{prp} - z}\right) = x \left(\frac{1}{1 - z/z_{prp}}\right)$$

$$y_{p} = y \left(\frac{z_{prp} - z_{vp}}{z_{prp} - z}\right) = y \left(\frac{d_{p}}{z_{prp} - z}\right)$$

$$y_{p} = y \left(\frac{z_{prp}}{z_{prp} - z}\right) = y \left(\frac{1}{1 - z/z_{prp}}\right)$$

#### Special Cases: The

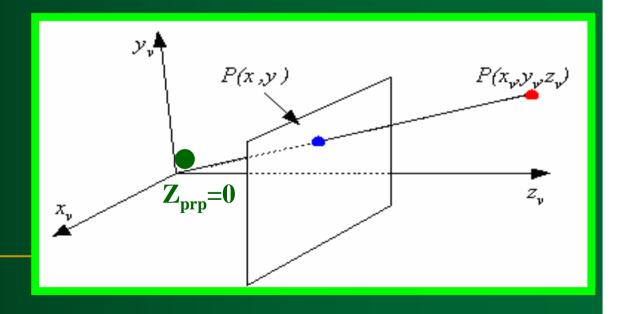

projection reference point is at the viewing coordinate origin:

$$z_{prp} = 0$$

$$x_{p} = x \left( \frac{z_{prp} - z_{vp}}{z_{prp} - z} \right) = x \left( \frac{d_{p}}{z_{prp} - z} \right)$$
$$y_{p} = y \left( \frac{z_{prp} - z_{vp}}{z_{prp} - z} \right) = y \left( \frac{d_{p}}{z_{prp} - z} \right)$$

$$x_{p} = x \left( \frac{z_{vp}}{z} \right) = x \left( \frac{1}{z/z_{vp}} \right)$$

$$y_{p} = y \left( \frac{z_{vp}}{z} \right) = y \left( \frac{1}{z/z_{vp}} \right)$$

## Summary
